

OVERVIEW OF RADIOLOGICAL MODALITIES FOR ORTHOPEDICS

DR. ZAINAB VORA

TARGET
ORTHO

MD RADIOLOGY (AIIMS)

(C) www.targetortho.com

INTRODUCTION

- ▶ Various imaging modalities available to evaluate the **presence, type and extent** of bone, joint and soft-tissue abnormalities
- ▶ The choice of techniques dictated by **clinical presentation** as well as **equipment availability, expertise, and cost**
- ▶ X-ray findings help decide further line of diagnostic algorithm and management in most cases

IMAGING MODALITIES

Radiographs

▶ Most frequently used as initial investigation

-TRAUMA

-TUMORS

-ARTHRITIS

▶ Convenient

▶ Inexpensive

▶ 2D technique

▶ Radiation +

Radiographs

Obtain at least two orthogonal views including two adjacent joints

Radiographs

- ▶ Oblique and special views, particularly in evaluating complex structures
- ▶ Weight-bearing view for a dynamic evaluation of the joint space under the weight of the body
- ▶ Radiograph of the normal unaffected limb for comparison is needed in paediatrics

OBLIQUE VIEW

Digital Radiography

- ▶ Used routinely nowadays
- ▶ Post-processing ++
- ▶ Contrast and brightness optimization
- ▶ Quantitation of image information
- ▶ Facilitation of examination storage and retrieval
- ▶ Energy subtraction imaging possible to reconstruct a soft-tissue-only image or a bone-only image.

Edge enhancement

Stress Views

- ▶ Important in evaluating ligamentous tears and joint stability
- ▶ Abduction-stress film of the thumb for gamekeeper's thumb
- ▶ The evaluation of knee and ankle instability caused by ligament injuries

USG

- ▶ Readily available
- ▶ Inexpensive
- ▶ Dynamic evaluation possible
- ▶ No radiation
- ▶ User-dependent
- ▶ Excellent for superficial soft tissues such as tendons and muscles
- ▶ Solid vs cystic
- ▶ Best for image guided procedures

USG of tendons

CT

- ▶ Excellent for bone and cortical evaluation
- ▶ Readily available
- ▶ Involves radiation
- ▶ High contrast resolution
- ▶ Post-processing, VRT imaging
- ▶ CT Angiography allows evaluation of associated vascular injury

VRT

- ▶ 3D volume rendered images
- ▶ Volumetric data can be reconstructed in any plane
- ▶ Suitable for 3D printing

MRI

- ▶ Highest soft tissue contrast resolution
- ▶ No radiation
- ▶ Expensive
- ▶ Not readily available
- ▶ Gold standard for most conditions

MRI

- ▶ Best for soft tissue evaluation such as ligaments, cartilage
- ▶ Best to pick up occult fractures
- ▶ Sensitive to pick up bone marrow edema, acute osteomyelitis

Persistent right hip pain

Persistent right hip pain

Bone Scan

- ▶ Tc99-Methylene diphosphonate
- ▶ 3-4hr delayed scan
- ▶ Multiple phase scan possible
- ▶ Sensitive study for bony pathologies such as:
 - Osteomyelitis
 - Metastases
 - Occult fracture
- ▶ Cold spot: Multiple myeloma
- ▶ Usually non-specific as an isolated test

Bone metastases

NaF PET
18-FDG PET
MRI
Bone scan

Arthrography

- ▶ Localise joint space under fluoroscopy
- ▶ Insert needle into joint along axis of xray beam
- ▶ Confirm intraarticular position by injection of contrast
- ▶ Iohexol used most commonly
- ▶ Volume of total contrast depends on joint (5-20cc)

MR Arthrography

- ▶ 0.1ml Gadolinium mixed with 5ml iodinated contrast media and 10ml saline and may be 5ml 1% lidocaine
- ▶ Adds to conventional MR imaging by delineating intraarticular structures such as labrum, cartilage, capsule and ligaments
- ▶ Contrast solution distends the joint capsule, outlines intraarticular structures, fills tears and leaks through them into the extra articular space

SPECIFIC CONDITIONS

IMAGING ARTHRITIS

Xray:

- ▶ Still the most widely used investigation
- ▶ Skeletal survey – disease distribution
- ▶ Treatment monitoring
- ▶ Not sensitive for early disease

IMAGING ARTHRITIS

USG:

- ▶ Joint effusion
- ▶ Synovial thickening & hypervascularity
- ▶ Erosions
- ▶ Monitor disease activity & progression
- ▶ Guided aspiration & injections

IMAGING ARTHRITIS

CT

- ▶ Limited role
- ▶ Imaging of CV junction
- ▶ Better demonstration of new bone formation and bony ankylosis

IMAGING ARTHRITIS

MRI

- ▶ Gold standard for synovial imaging
- ▶ Detection of active synovitis
- ▶ Bone marrow changes
- ▶ Early detection of erosions

(MRI erosions progress to radiographical erosions with in 2 yrs)

IMAGING TUMORS

Xray:

- ▶ Most important modality for diagnosis
- ▶ Location
- ▶ Matrix
- ▶ Pattern of destruction
- ▶ Periosteal reaction
- ▶ Solitary or multiple

IMAGING TUMORS

CT:

- ▶ Complex skeletal anatomy (e.g., spine, pelvis, scapula)
- ▶ Superior delineation of cortical
- ▶ Detection of subtle matrix calcifications

IMAGING TUMORS

MRI:

- Extent of tumor in marrow and soft tissues
- Neurovascular bundle involvement
- Skip lesions
- Joint involvement
- Assessing response to chemotherapy
- Tumour recurrence

IMAGING NERVES

ULTRASOUND

- ▶ Higher spatial resolution
- ▶ Real time dynamic evaluation, especially in entrapment syndrome.
- ▶ Longer coverage (entire nerve) in short time.
- ▶ Comparison with contralateral side – easy.

IMAGING NERVES

MRI

- ▶ High diagnostic confidence
- ▶ Not operator dependent
- ▶ Areas of dense scarring/ architectural distortion
- ▶ Secondary denervation changes.

Conclusion

- ▶ Wide array of investigations available at disposal
- ▶ Key to choose the best examination will depend on clinical manifestations and findings on initial investigation
- ▶ X-ray: Initial investigation of choice
- ▶ USG: Useful for dynamic evaluation of joints, solid vs cystic evaluation, guiding interventions
- ▶ CT: Best for evaluating fractures, cortical thickening
- ▶ MRI: Best for soft tissues, cartilage, ligaments, bone marrow edema
- ▶ Bone scan: Role in occult fractures, acute osteomyelitis, metastases
- ▶ Fluoroscopy: Guides interventions such as biopsy, angiography, arthrography

Thank you!
